# Install Haskell and your first program Guess Number

### 1.1 Build Tools

### 1.1.1 Stack

https://docs.haskellstack.org/en/stable/README/
make sure 'stack -version' outputs latest stack version, currently 'Version 1.6.5'.
'stack upgrade'
Add Nix and Cabal

### 1.2 Editor Integration

VScode with haskell-ide-engine Haskell Syntax Highlight

### 1.2.1 Haskell IDE Engine

[haskell-ide-engine](https://github.com/haskell/haskell-ide-engine)
Install on MacOS, you need to install 'icu4c' on your machine.
git clone https://github.com/haskell/haskell-ide-engine cd haskell-ide-engine make
"bash stack install hoogle
hoogle generate stack install "
Stack
"bash stack version
stack upgrade "

### 1.3 Your first haskell program

stack new guessNumber

## CHAPTER 1. INSTALL HASKELL AND YOUR FIRST PROGRAM GUESS 1.3. YOUR FIRST HASKELL PROGRAM NUMBER

```
module Main where
import
                 Control.Monad
import
                 Data.Ord
                                (compare)
                 System.IO
                                (readLn)
import
import
                 System.Random (randomRIO)
guess :: Int -> IO ()
guess secretNumber = do
    print "guess a number"
    guessNumber <- readLn :: IO Int</pre>
    case compare guessNumber secretNumber of
        LT -> (print "Too Small!") >> (guess secretNumber)
        EQ -> print "You Win!"
        GT -> (print "Too big!") >> (guess secretNumber)
main :: IO ()
main = do
    secretNumber <- randomRIO (0, 100) :: IO Int</pre>
    guess secretNumber
```

## Chapter 2

## From State to Monad Transformers

### 2.1 State Monad

First, let's look what is State.

```
newtype State s a = State { runState :: s-> (a, s)}
```

In case you are not familiar with newtype. It is just like 'data' but it can only \*has exactly one constructor with exactly one field in it.\* In this case 'State' is the constructor and 'runState' is the single field. The type of 'State' constructor is '(s -> a, s)) -> State s a', since 'State' uses record syntax, we have a filed accessor 'runState' and its type is State s a -> s -> (a, s). "A State is a function from a state value" to (a produced value <strong><em>a</em></strong>, and a resulting state <strong><em>s</em></strong>).</blockquote> An importance takeaway which might not so oblivious to Haskell beginner is that: 'State' is merely a function with type 's -> (a,s)', (a function wrapped inside constructor 'State', to be exact, and we can unwrap it using 'runState').

Secondly, 'State' function takes a 's'representing a state, and produces a tuple contains value 'a' and new state 's'.

exec

The first exercise is to implement 'exec' function, it takes a 'State' function and initial 'state' value, returns the new state.

It is pretty straightforward, we just need to apply 'State' function with 'state' value, and takes the second element from the tuple.

A simple solution can be

```
exec :: State s a \rightarrow s \rightarrow s exec f initial = (\ (_, y) \rightarrow y) (runState f initial)
```

Since the state value 'initial' appears on both sides of '=', we rewrite it a little more point-free. 'runState f' is a partial applied function takes 's' returns '(a,s)'

### 2.1. STATE MONADCHAPTER 2. FROM STATE TO MONAD TRANSFORMERS

```
exec f = (\(_, y) -> y) . runState f
exec f = P.snd . runState f

We could also write 'exec'
  'exec (State f) = P.snd . f'
```

### **2.1.1** Basic Usage of State

```
module Dice where
import Control.Applicative
import Control.Monad.Trans.State
import System.Random
rollDiceIO :: IO (Int, Int)
rollDiceIO = liftA2 (,) (randomRIO (1, 6)) (randomRIO (1,6))
rollNDiceIO :: Int -> IO [Int]
rollNDiceIO 0 = pure []
rollNDiceIO count = liftA2 (:) (randomRIO (1, 6)) (rollNDiceIO (count - 1))
clumsyRollDice :: (Int, Int)
clumsyRollDice = (n, m)
    where
        (n, g) = randomR (1, 6) (mkStdGen 0)
        (m, _) = randomR (1, 6) g
-- rollDice :: StdGen -> ((Int, Int), StdGen)
-- rollDice g = ((n, m), g'')
       where
           (n, q') = randomR(1, 6) q
           (m, g'') = randomR (1, 6) g'
-- use state to construct
rollDie :: State StdGen Int
rollDie = state $ randomR (1, 6)
-- use State as Monad
rollDieM :: State StdGen Int
rollDieM = do generator <- get</pre>
              let (value, generator') = randomR (1, 6) generator
              put generator'
              return value
rollDice :: State StdGen (Int, Int)
```

```
rollDice = liftA2 (,) rollDieM rollDieM
rollNDice :: Int -> State StdGen [Int]
rollNDice 0 = state (\s -> ([], s))
rollNDice count = liftA2 (:) rollDieM (rollNDice (count - 1))
  How about draw card from a deck
module Deck where
import Control.Applicative
import Control.Monad.Trans.State
import Data.List
import System.Random
data Rank = One | Two | Three | Four | Five | Six | Seven | Eight | Nine | Ten | Jack | Queue | F
data Suit = Diamonds | Clubs | Hearts | Spades deriving (Bounded, Enum, Show, Eq, Ord)
data Card = Card Suit Rank deriving (Show, Eq, Ord)
type Deck = [Card]
fullDeck :: Deck
fullDeck = [Card suit rank | suit <- enumFrom minBound,</pre>
                              rank <- enumFrom minBound]</pre>
removeCard :: Deck -> Int -> Deck
removeCard [] _ = []
removeCard deck index = deck' ++ deck''
    where (deck', remain) = splitAt (index + 1) deck
          deck'' = drop 1 remain
drawCard :: State (StdGen, Deck) Card
drawCard = do (generator, deck) <- get</pre>
              let (index, generator') = randomR (0, length deck ) generator
              put (generator', removeCard deck index)
              return $ deck !! index
drawNCard :: Int -> State (StdGen, Deck) [Card]
drawNCard 0 = state (\s -> ([], s))
drawNCard count = liftA2 (:) drawCard (drawNCard $ count - 1)
```

How about folding a list using 'State' https://github.com/yuanw/applied-haskell/blob/2018/monad-transformers.mdhow-about-state

#### 2.2. MONAD TRAN**SFIGNITURES.** FROM STATE TO MONAD TRANSFORMERS

```
foldState :: (b -> a -> b) -> b -> [a] -> b
foldState f accum0 list0 =
    execState (mapM_ go list0) accum0
    where
    go x = modify' (\accum -> f accum x)
```

### 2.2 Monad Transformers

### 2.2.1 Motivation

Why we cannot compose any two monad

https://stackoverflow.com/questions/7040844/applicatives-compose-monads-dont

### 2.2.2 Build a composed monad by hand

```
newtype StateEither s e a = StateEither
    { runStateEither :: s -> (s, Either e a)
    }

Let's implement the functor instance of this typeP
    References https://en.wikibooks.org/wiki/Haskell/Understanding_monads/
```

State https://haskell.fpcomplete.com/library/rio

### **Chapter 3**

## **Learning Lens**

Lenses, Folds, and Traversals What is a Lens? Lenses address some part of a "structure" that always exists, either look that part, or set that part. "structure" can be a computation result, for example, the hour in time. Functional setter and getter. Data.Lens

view looks up an attribute a from s view is the getter, and set is the setter. Laws 1. set 1 (view 1 s) s = s 2. view 1 (set 1 s a) = a 3. set 1 (set 1 s a) b = set 1 s b Law 1 indicates lens has no other effects since set and view in Lens both start with  $s \rightarrow$ , so we can fuse the two functions into a single function 's  $\rightarrow$  (a  $\rightarrow$  s, a)'.

So we could define Lens as "haskell data Lens s a = Lens (s -> (a -> s), a) data Store s a = Store (s -> a) s data Lens s a = Lens (s -> Store a s) "

Side bar Store Comonad urlhttps://stackoverflow.com/questions/8428554/what-is-the-comonad-typeclass-in-haskell hurlttps://stackoverflow.com/questions/8766246/what-is-the-store-comonad

Lens can form a category

Semantic Editor Combinator

                (.).(.) :: (b \rightarrow c) \rightarrow (a \rightarrow b) \rightarrow a \rightarrow c (dotF \cdot dotG :: (b \rightarrow c) \rightarrow (a \rightarrow c) \rightarrow a \rightarrow c
  'dotF :: b -> c' 'dotG :: a -> b'
                since 'dotF' is just an alias to '(.)' 'dotF:: (u -> v) -> (s -> u) -> s -> v' '(u -> v) ->
 (s \rightarrow u) \rightarrow s \rightarrow v === b \rightarrow c' therefore 'b === (u \rightarrow v)' 'c === (s \rightarrow u) \rightarrow s \rightarrow v'
                'dotG' is also an alias to '(.)' 'dotG :: (y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow x \rightarrow z' '(y \rightarrow z) \rightarrow (x \rightarrow y) \rightarrow (x
-> y) -> x -> z === a -> b' therefore 'a === (y -> z)' 'b === (x -> y) -> x -> z'
               since 'b' appears on both side
               " a === y -> z b === (u -> v) b === (x -> y) -> x -> z c === (s -> u) -> s -> v"
                we can deduct
                "" u === x -> y v === x -> z ""
               therefore 'c === (s -> x -> y) -> s -> x -> z'
                (.).(.) === a -> c (.).(.) === (y -> z) -> (s -> x -> y) -> s -> x - z (.).(.)
                we can generalize this to any functor
                                                                                                        :: Functor f \Rightarrow (a \rightarrow b) \rightarrow f a \rightarrow f b
 fmap
                                                                                                        :: (Functor f, Functor g) \Rightarrow (a \rightarrow b) \rightarrow f (g a) \rightarrow f (g b)
 fmap . fmap
fmap . fmap .: (Functor f, Functor g, Functor h) => <math>(a \rightarrow b) \rightarrow f (g (h a)) \rightarrow
                it means we compose a function under arbitrary level deep nested context Semantic
Editor Combinator
                'type SEC s t a b = (a \rightarrow b) \rightarrow s \rightarrow t' it like a functor (a \rightarrow b) \rightarrow f a \rightarrow f b 'fmap' is
Semantic Editor Combinator 'fmap . fmap' is also a SEC
                so we use 's' to generalize 'f a', 'f (g a)', 'f (g (h a))' and 't' to generalize 'f b', 'f
(g b)', 'f (g (h b))'. It may seems counterintuitive at first, we lost the relation between
a and s, b and t. Functor is a semantic Editor Combinator 'fmap:: Functor f => SEC (f
a) (f b) a b'
                first is a also SEC? "haskell first: SEC (a, c) (b,c) a b first f (a, b) = (f a, b) "
Setters We can compose Traversable the way as we can compose '(.)' and 'fmap'
                "haskell traverse :: (Traversable f, Applicative m) => (a -> m b) -> f a -> m (f
b) traverse: (Traversable f, Traversable g, Applicative m) => (a -> m b)
-> f (g a) -> m (f (g b)) traverse . traverse :: (Traversable f, Traversable g,
Traversable h, Applicative m) => (a \rightarrow m b) \rightarrow f(g(h a)) \rightarrow m(f(g(h b))) ""
                traverse is a generalized version of mapM, and work with any kind of Foldable not
just List.
                "' class (Functor f, Foldable f) => Traversable f where traverse :: Applicative m =>
(a -> m b) -> f a -> m (f b) ""
               "haskell fmapDefault :: forall t a b. Traverable t \Rightarrow (a \Rightarrow b) \Rightarrow t a \Rightarrow t b fmapDe-
fault f = runIndentity . traverse (Identity . f) ""
               build 'fmap' out from traverse we can change 'fmapDefault'
over 1 f = runIdentity . 1 (Identity . f)
over traverse f = runIdentity . traverse (Identity . f)
                                                                                    = fmapDefault f
                                                                                    = fmap f
```

```
type of 'over:: ((a \rightarrow Identity b) \rightarrow s \rightarrow Identity t) \rightarrow (a \rightarrow b) \rightarrow s \rightarrow t' type Setter
s t a b = (a \rightarrow Identity b) \rightarrow s \rightarrow Identity t so we could rewrite 'over' as over:: Setter s
t a b \rightarrow (a \rightarrow b) \rightarrow s \rightarrow t let's apply setter
mapped :: Functor f => Setter (f a) (f b) a b
mapped f = Identity . fmap (runIdentity . f)
over mapped f = runIdentity . mapped (Identity . f)
